According to the decompilation of the Ciso Vigenere hash algorithm, when the password length is less than 16 the idea behind Ciso Vigenere hash algorithm is:

Let p be the password that the user types.

Let hp be the hardcoded password in the code of Packet Tracer.

Let lp be the length of the user input password.

Let h be the hash value obtained from the custom algorithm.

So that:

```
 \forall h \forall l p \forall h p [(hp = (d, s, f, d, ;, k, f, o, A, ,, ., i, y, e, w, r, k, l, d, J, K, D, H, S, U, B, s, g, v, c, a, 6, 9, 8, 3, 4, n, c, x, v), \\ 0 < lp < 16, \\ h_0 = 0, \\ h_1 = 8, \\ h = \\ \sum_{i=2}^{lp} \begin{cases} ((p_i \oplus hp_{8+i}) \ggg 4) + 0x30, & \text{if } (h_i \oplus hp_{i+8} \land 0xffffffff 0 < 0xa0) \text{ and if } i \equiv 0 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \ggg 4) + 0x37, & \text{if } (h_i \oplus hp_{i+8} \land 0xffffffff 0 \ge 0xa0) \text{ and if } i \equiv 0 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \land 0xf) + 0x30, & \text{if } (h_i \oplus hp_{i+8} \land 0xf < 0x0a) \text{ and if } i \equiv 1 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \land 0xf) + 0x37, & \text{if } (h_i \oplus hp_{i+8} \land 0xf \ge 0x0a) \text{ and if } i \equiv 1 \pmod{2} \\ ) \implies \nexists p[p = \mathbf{rev}(h)](0)
```

Let's start by prooving

```
 \forall h \forall l p \forall h p [(hp = (d, s, f, d, ;, k, f, o, A, , ., ., i, y, e, w, r, k, l, d, J, K, D, H, S, U, B, s, g, v, c, a, 6, 9, 8, 3, 4, n, c, x, v), \\ 0 < lp < 16, \\ h_0 = 0, \\ h_1 = 8, \\ h = \\ \sum_{i=2}^{lp} \begin{cases} ((p_i \oplus hp_{8+i}) \ggg 4) + 0x30, & \text{if } (h_i \oplus hp_{i+8} \land 0xffffffff 0 < 0xa0) \text{ and if } i \equiv 0 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \ggg 4) + 0x37, & \text{if } (h_i \oplus hp_{i+8} \land 0xffffffff 0 \geq 0xa0) \text{ and if } i \equiv 0 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \land 0xf) + 0x30, & \text{if } (h_i \oplus hp_{i+8} \land 0xf < 0x0a) \text{ and if } i \equiv 1 \pmod{2} \\ ((p_i \oplus hp_{8+i}) \land 0xf) + 0x37, & \text{if } (h_i \oplus hp_{i+8} \land 0xf \geq 0x0a) \text{ and if } i \equiv 1 \pmod{2} \end{cases}
```

$$) \Longrightarrow \nexists p[p = \mathbf{rev}(h)]$$
(0)

I/ substraction to reverse the addition

 $\forall x[(x=y+z) \Longrightarrow (y=ez)]$  then it follow that as the previous part of the function contains: h=x+0x30, then h-0x30=x so  $\exists rev(h)[rev(H(p))=p-0x30]$ 

II/ exclusive or

According to the boolean algebra about the exclusive logical or operation,  $\forall x[y=(x\oplus x)\implies (y=0)].$ 

Then as xlat  $\oplus xlat = 0$ , and as  $p \oplus 0 = p$ , we know that the original password  $p = (xlat \oplus h)$ .

III/ rotating 4 first to 4 last bits

 $\forall x[(x \ggg y) \implies (x \lll y = x)].$ 

Then as  $z = (x \gg y) = (x \ll y)$ , we know that the original password  $p = H(p) \ll 4$ .

 $\ensuremath{\mathrm{IV}}/$  unmasking different signatures (recurrent marks) in the password modification

In the previous chapter one 'I/ substraction to reverse the addition', we told we can reverse the previous addition. We still need to guess which addition/substraction has been done previously.

As both addition values are made depending to: if

 $(p_l \wedge 0xf0 < 0xa0) \implies (p_l \wedge 0xf0 + 0x30)$  or else

 $(p_l \wedge 0xf0 > 0xa0) \implies (p_l \wedge 0xf0 + 0x37)$ 

 $if (p_r \wedge 0x0f < 0x0a) \implies (p_r \wedge 0x0f + 0x30)$  or else

 $(p_r \wedge 0x0f > 0xa0) \implies (p_r \wedge 0x0f + 0x37)$ 

So if the out has the 4 four bits value so that:

 $x \in x | (0xf0x) \le 0xa0 \implies y = x + 0x30$ 

So if the out has the 4 four bits value so that:

 $x \in x | (0xf0x) > 0xa0 \implies y = x + 0x37$ 

So if the out has the 4 four first bits value so that:

 $x \in x | (0x0fx) \le 0x0a \implies y = x + 0x30$ 

```
So if the out has the 4 four first bits value so that:
x \in x | (0x0fx) > 0x0a \implies y = x + 0x37
first byte:
as 0xa0 < 0xf0 + 0x30 < y
-1: \forall y \in H(x) [(x \in \{x | 0xa0 < x\}) \implies (y \in \{y | 0x00 < y < 0xa7\})]
-2: \forall y \in H(x)[(x \in \{x | x < 0xa0\}) \implies (y \in \{y | 0xc0 < y\})]
second byte: as 0xa0 < 0x0f + 0x30 < y
-1: \forall y \in H(x)[(x \in \{x | x < 0x0a\}) \implies (y \in \{y | 0x3a < y\})]
-2: \forall y \in H(x)[(x \in \{x | 0x0a < x\}) \implies (y \in \{y | y < 0x4a\})]
Then for both of any subnumber: that
\forall y = H(x), x \in \{x | x \le 0xa\} \implies y = x + 0x30
andthat \forall y = H(x), x \in \{x | x > 0xa\} \implies y = x + 0x37
that \forall y = H(x)[(y \in \{y | 0 < y \le 0x0a + 0x30\}) \implies (x = y - 0x30)] then
0 < x < 0x0a
and that \forall y = H(x)[(y \in \{y | 0 < y \le 0x0a + 0x37\}) \implies (x = y - 0x30)] then
0x0a \le x
V /communitativity:
Addition, substraction and \oplus are commutative.
VI / proof
Then we have already proven each piece of the theorem so that: hp =
(d, s, f, d, ; k, f, o, A, , ..., i, y, e, w, r, k, l, d, J, K, D, H, S, U, B, s, g, v, c, a, 6, 9, 8, 3, 4, n, c, x, v) \Longrightarrow
(\forall x \in hp[0 \ge x0 \ge 256 \implies x \in hp])
then:
Let p be the password that the user types.
Let hp be the hardcoded password in the code of Packet Tracer.
Let lp be the length of the user input password.
Let h be the hash value obtained from the custom algorithm.
So that:
```

 $\forall h \forall lp \forall hp [(hp \in N \land 0 \ge hp,$ 

0 < lp < 16,

```
\begin{array}{l} \mathbf{h}_0 = 0, \\ \mathbf{h}_1 = 8, \\ \mathbf{h} = \\ \sum_{i=2}^{lp} \begin{cases} (((p_i \oplus hp_{i+8}) \lll 4) - 0x30), & \text{if } h_i < 0xa0 \text{ and if } i \equiv 0 \pmod{2} \\ (((p_i \oplus hp_{i+8}) \lll 4) - 0x37), & \text{if } h_i \geq 0xa0 \text{ and if } i \equiv 0 \pmod{2} \\ (((p_i \oplus hp_{i+8}) \wedge 0xfffffffff0) - 0x30), & \text{if } h_i < 0x0a \text{ and if } i \equiv 1 \pmod{2} \\ (((p_i \oplus hp_{i+8}) \wedge 0xfffffffff0) - 0x37), & \text{if } h_i \geq 0x0a \text{ and if } i \equiv 1 \pmod{2} \\ ) \implies \forall p[p = \mathbf{rev}(h)] \end{array}
```
